Distributed CVR in Unbalanced Distribution Systems With PV Penetration

Qianzhi Zhang[®], *Student Member, IEEE*, Kaveh Dehghanpour[®], *Member, IEEE*, and Zhaoyu Wang[®], *Member, IEEE*

Abstract-In this paper, a distributed multi-objective ² optimization model is proposed to coordinate the fast-dispatch 3 of photovoltaic (PV) inverters with the slow-dispatch of on-load 4 tap changer and capacitor banks for implementing conservation ⁵ voltage reduction in unbalanced three-phase distribution systems. 6 In existing studies, PV inverters and voltage regulation devices 7 are generally dispatched by fully centralized control frameworks. 8 However, centralized optimization methods are subject to single 9 point of failure and suffer large computational burden. To tackle 10 these challenges, a distributed dispatch method is developed 11 to coordinate PV inverters and conventional voltage regulation 12 devices in distribution systems. The proposed method is based on 13 a modified alternating direction method of multipliers algorithm 14 to handle non-convex optimization problems without relaxing 15 the original formulation, which could lead to sub-optimality. 16 Numerical results from simulations on modified IEEE 13-bus, 17 34-bus, and 123-bus unbalanced three-phase systems have been 18 used to verify the proposed method.

19 *Index Terms*—Conservation voltage reduction, distributed dis-20 patch, multi-objective optimization, photovoltaic inverters, volt-21 age regulation.

NOMENCLATURE

22

AO1

23 Sets and Indices

- ²⁴ Ω_N Set of buses
- ²⁵ Ω_i Set of buses connected to bus *i*
- ²⁶ Ω_T Set of dispatch period T
- ²⁷ Ω_{ϕ} Set of phases a, b, c.

28 Parameters

29	α_i	Unbalanced phase factor of bus <i>i</i>
30	$\theta_{i_b}, \theta_{i_c}$	Phase angle differences at bus <i>i</i> relative to phase
31		angle θ_{i_a}
32	w_1, w_2	Weight factors in multi-objective optimization
33		problem
34	$P_{i,t,\phi}^{PV}$	Injected active power of PV of bus i , at time t ,
35		for phase ϕ

I. INTRODUCTION

▼ONSERVATION voltage reduction (CVR) is a viable 91 technique used by utilities for peak shaving and long-92 93 term energy savings. CVR is achieved by controlled voltage 94 level decrease of voltage-sensitive customers [1]. A conven-95 tional approach for implementing CVR is by adjusting tap 96 positions of On-Load Tap Changer (OLTC) at the substa-97 tion transformers, which ensures that the nodal voltages are ⁹⁸ reduced in a manner that neither violates the acceptable volt-⁹⁹ age ranges nor affects the performance of devices [2]. A more advanced way of implementation is to integrate CVR into 100 Volt/VAr optimization (VVO) models as an objective function, 101 which provide a framework for optimal control of voltage reg-102 ulation and VAr control devices to achieve specific operational 103 goals without violating any of the operational constraints. 104

VVO has been used for optimal control of conventional 105 Volt/VAr regulation devices, such as capacitor banks (CBs) 106 107 and OLTC [3], [4]. However, these conventional Volt/VAr reg-¹⁰⁸ ulation devices have slow reaction speed and limited number 109 of switching operations, which cannot handle the fast changes system states caused by increasing penetration of renew-110 in able energy resources (RES) in modern distribution systems. 111 While the implementation of CVR requires a relatively flat 112 voltage profile along the feeders in distribution systems, higher 113 penetration levels of RES will cause fast and uncertain volt-114 115 age fluctuations and deviations. On the other hand, PV smart 116 inverters have much higher response speed and more flexi-117 ble reactive power generation and absorption capabilities to 118 handle fast voltage deviations caused by uncertain RES out-¹¹⁹ put and load fluctuations. Therefore, to improve the efficiency voltage regulation and get a better performance for CVR 120 Of 121 implementation, modern VVO models are not only designed 122 to include optimal control of conventional Volt/VAr regulation 123 devices, but also control of PV smart inverters to facilitate voltage reduction [5]–[8]. 124

In previous VVO studies, a multi-timescale voltage regulation framework has been frequently applied as shown in Pig. 1. This framework separates dispatching of conventional Volt/VAr regulation devices and PV inverters, as they take place on different timescales. Following this multi-timescale voltage regulation framework, hourly dispatch of OLTC, CBs and 15-min dispatch of PV inverters are coordinated in our research.

¹³³ In general, three different optimization methods are applied ¹³⁴ in the multi-timescale VVO framework: 1) fully centralized

Fig. 1. Multi-timescale voltage regulation framework in VVO.

optimization methods, 2) hierarchical optimization methods, 135 and 3) fully distributed optimization methods. In [5]–[7], the 136 slow-dispatch of conventional voltage regulation devices and 137 the fast-dispatch of PV inverters are both solved by central- 138 ized optimization methods. Centralized optimization requires 139 the system-wide collection of data, and a costly communi- 140 cation infrastructure to enable information passing between a 141 control center and regulation devices [9], [10]. Moreover, these 142 methods are susceptible to single point of failure. Therefore, 143 fully centralized optimization models are disadvantageous due 144 to the increasing burden of computation in modern distribu- 145 tion systems with increasing size of decision models. A partial 146 solution to this problem is to adopt a hierarchical optimization 147 approach for VVO, as presented in [8], where the slow- 148 dispatch of conventional voltage regulation devices is solved 149 by a centralized optimization method, while a distributed 150 optimization technique is used to solve the fast-dispatch of PV 151 inverters. However, this VVO model divides the dispatching 152 model into two optimization problems, which cannot guarantee 153 the global optimality of the original optimization problem. 154

As discussed previously, fully centralized and hierarchical 155 methods are both impractical in large interconnected and com- 156 plex distribution systems. On the other hand, fully distributed 157 optimization methods represent an economically viable and 158 computationally simpler alternative to address the above- 159 mentioned challenges [11]. Distributed methods are applied 160 based on distributed optimization algorithms, which only 161 rely on local data collection and local information exchange 162 between neighboring control agents. Also, in contrast with 163 centralized methods that have a single point of failure, dis- 164 tributed optimization techniques are resilient against agent 165 communication failure and communication limits [12], [13]. 166 Besides, in distributed approaches, the data privacy and owner- 167 ship of customers are maintained, including local consumption 168 measurement data and cost functions [14]. Thus, a large-scale 169 optimization problem can be divided into a number of small- 170 scale optimization problems, which are efficiently coordinated 171 and solved by local agents to obtain a final solution for the 172 original problem. In recent studies, distributed optimization 173 methods have been largely applied to different power engineer- 174 ing applications, including distributed DC optimal power flow 175 in power transmission systems [13], [15], as well as distributed 176 optimal AC power flow in distribution networks [16], [17]. 177 Distributed optimization methods are also applied to voltage 178 regulation problems. For example, [18] introduces a VVO 179 model which only controls the optimal set-points of OLTC 180 devices, while [19] and [20] propose VVO models to optimally 181

¹⁸² dispatch PV inverters. Even though distributed optimization ¹⁸³ methods are applied in previous studies, the problem of ¹⁸⁴ PV inverter coordination with conventional voltage regulation ¹⁸⁵ devices using distributed optimization has remained largely ¹⁸⁶ unstudied, which leads to poor voltage regulation performance ¹⁸⁷ in the system.

To tackle this problem, in this paper a fully distributed 188 189 method is proposed to optimally coordinate the slow-dispatch 190 of conventional voltage regulation devices and the fast-¹⁹¹ dispatch of PV inverters in a unified optimization framework. The proposed distributed method in this research is developed 192 ¹⁹³ based on alternating direction method of multipliers (ADMM). ¹⁹⁴ ADMM was originally applied to solve convex problems by ¹⁹⁵ minimizing the decomposed augmented Lagrangian function ¹⁹⁶ associated with each control area in an iterative way [21]. 197 However, control actions in VVO problems, such as the oper-¹⁹⁸ ation statues of CVs and tap position of OLTCs, can only 199 be accurately modeled as discrete variables. Even though the ²⁰⁰ existence of a theoretical convergence guarantees for ADMM in non-convex cases is still an open problem [22], some 201 202 modifications to ADMM can be made to find local minimums for non-convex problem. A simple solution to address 203 problem non-convexity is to perform optimization relaxation 204 by replacing discrete variables with continuous variables in the 205 ²⁰⁶ distributed algorithm [23]. However, this approach may not be able to ensure a high quality solution. A more reasonable mod-207 208 ification method is proposed in [24] and used in this paper, where the discrete variables are not only replaced and relaxed 209 210 by continuous variables, but also integrated into the ADMM 211 objective function. This modified ADMM solver is able to ²¹² avoid changing the structure of the original non-convex deci-²¹³ sion model, which reduces the risk of solution sub-optimality. When implementing CVR using VVO, the objective is 214 215 usually set to minimize the bus voltage magnitudes with-216 out violating bus voltage limits to reduce power consump-217 tion. However, due to lower bus voltages, the system power 218 losses will increase [25], which is in conflict with the gen-219 eral objective of VVO, i.e., minimization of system power losses. Therefore, VVO-based CVR implementation requires 220 trade-off between voltage reduction and real power loss 221 a 222 reduction, which needs to be quantified. In this research, multi-objective optimization formulation is developed to 223 a 224 quantify this trade-off relationship. By changing the user-225 defined weight factors in the multi-objective function, the 226 importance levels of bus voltage minimization for CVR and 227 network power loss minimization will be controlled. The 228 proposed method is tested on three test systems with dif-229 ferent number of nodes (IEEE 13-bus, 34-bus, and 123-bus 230 systems). Numerical results show the superior performance 231 of the proposed distributed optimization model compared to 232 conventional centralized approaches in terms of computational 233 speed and solution quality.

The main contributions of this research can be summarized as follows:

• An optimization model is developed to coordinate the fast-dispatch of PV inverters with the slow-dispatch of

- OLTC and CBs, in order to facilitate voltage reduction in
- unbalanced three-phase distribution systems.

Fig. 2. Schematic diagram of a radial distribution system.

- In order to ensure the solution optimality and main- ²⁴⁰ tain customer data privacy and ownership, a distributed ²⁴¹ solution methodology is proposed to dispatch all the ²⁴² above-mentioned devices in a unified optimization frame- ²⁴³ work. The solution methodology is based on a modified ²⁴⁴ ADMM technique to handle the non-convex optimization ²⁴⁵ problem with discrete switching and tap changing ²⁴⁶ variables. ²⁴⁷
- The trade-off between voltage reduction and real power ²⁴⁸ loss reduction is quantified numerically using the devel- ²⁴⁹ oped multi-objective VVO formulation. ²⁵⁰

The organization of this paper is as follows: Section III ²⁵¹ introduces the unbalanced three-phase distribution system ²⁵² model and formulates the optimal coordination of PV invert- ²⁵³ ers with OLTC and CBs. Section IV discusses the modified ²⁵⁴ ADMM to handle non-convex discrete variables, and shows ²⁵⁵ the operation of the modified ADMM. Simulation results and ²⁵⁶ conclusions are presented in Sections V and VI, respectively. ²⁵⁷

II. CENTRALIZED COORDINATION OF PVS WITH 258 CONVENTIONAL VOLTAGE REGULATION DEVICES 259

In this section, we develop a multi-objective optimization 260 model to coordinate the fast-dispatch of PV inverters with the 261 slow-dispatch of OLTC and CBs in unbalanced three-phase 262 distribution systems. The DistFlow equations and ZIP load 263 models are also introduced. The presented model in this section will be then used in Section IV to design a distributed 265 solution strategy for VVO-based CVR. 266

A. Distribution System Model

267

To obtain the power flow solution in a radial distri- ²⁶⁸ bution network, the DistFlow equations have been widely ²⁶⁹ used [26], [27]. A typical radial distribution system is shown ²⁷⁰ in Fig. 2, where the bus indexes are denoted as i = 271 $\{0, 1, 2, ..., n\}$.

The DistFlow equations can be presented as 273 equations (1)-(5). In (1)-(3) the nonlinear terms are much 274 smaller than the linear terms and can be ignored. In practice, 275 this linear form of DistFlow has been verified in many 276 previous studies such as [20], [27]. 277

$$P_{i+1}^{l} = P_{i}^{l} - r_{i} \frac{\left(P_{i}^{l}\right)^{2} + \left(Q_{i}^{l}\right)^{2}}{V_{i}^{2}} - p_{i+1}$$
(1) 278

$$Q_{i+1}^{l} = Q_{i}^{l} - x_{i} \frac{(Q_{i}^{l})^{2} + (Q_{i}^{l})^{2}}{V_{i}^{2}} - q_{i+1}$$
(2) 279

289

 TABLE I

 ZIP COEFFICIENTS FOR EACH CUSTOMER TYPE [28]

Bus Type	Zp	Ip	Рр	Zq	Iq	Pq
Commercial	0.43	-0.06	0.63	4.06	-6.65	4.49
Residential	0.85	-1.12	1.27	10.96	-18.73	8.77
Industrial	0	0	1	0	0	1

$$V_{i+1}^{2} = V_i^2 - \frac{2(r_i P_i^l + x_i Q_i^l)}{V_s} + (r_i^2 + x_i^2) \frac{(P_i^l)^2 + (Q_i^l)^2}{V_i^2}$$
(3)

In (4) and (5), P_{i+1}^g is the active power generated by PVs at bus i + 1. Q_{i+1}^g is the reactive power generated by VAR compensation devices at bus i+1. In the proposed model, PV set inverters and CBs are considered as reactive power sources. P_{i+1}^d and Q_{i+1}^d are active power and reactive demand load at bus i + 1, which will be modeled as ZIP active and reactive loads (refer to Section II-C).

288
$$p_{i+1} = P_{i+1}^d - P_{i+1}^g \tag{4}$$

$$q_{i+1} = Q_{i+1}^d - Q_{i+1}^g.$$
⁽⁵⁾

290 B. Extension to Unbalanced Systems

To better model distribution systems, we will extend the power flow model to unbalanced three-phase systems using a simplified model [19], which can approximate phase imbalances. It is assumed that the voltage magnitudes of the three phases at bus *i* are similar, so that $|V_{i_a}| \approx |V_{i_b}| \approx |V_{i_c}|$. Then with the voltage phase angles $\theta_{i_a} = 0$, θ_{i_b} , and θ_{i_c} , the relative phase unbalance α_i is approximated as follows:

$$\alpha_i = \left[1, e^{j\theta_{i_b}}, e^{j\theta_{i_c}}\right]^T \tag{6}$$

Therefore, we can apply the relative phase unbalance α_i of bus *i* as follows: the equivalent unbalanced three-phase system in line impedance $z_{i,\phi}$ can be calculated in (7) based on α_i and ine impedance z_i . The real and imaginary parts of $z_{i,\phi}$ are and the unbalanced three-phase system line resistance $r_{i,\phi}$ in (8) and unbalanced three-phase system line reactance $x_{i,\phi}$ in (9), respectively. Therefore, the DistFlow equations (1)-(3) can be extended to unbalanced three-phase by replacing $r_{i,\phi}$ and $x_{i,\phi}$ in (8)-(9). The load applied in this paper is also unbalanced.

$$z_{i,\phi} = \alpha_i \alpha_i^H \odot z_i \tag{7}$$

$$r_{i,\phi} = real(z_{i,\phi})$$

$$x_{i\phi} = imag(z_{i\phi}). \tag{9}$$

311 C. ZIP Load Model

In our VVO formulations, the loads are represented using 312 In our VVO formulations, the loads are represented using 313 ZIP load models which include constant-impedance (Z), 314 constant-current (I), and constant-power components (P). Z_i^p , 315 I_i^p , P_i^p and Z_i^q , I_i^q , P_i^q are constant-impedance coefficients, 316 constant-current coefficients and constant-power coefficients 317 for active and reactive loads, respectively. In [28] and [29] 318 typical ZIP coefficients for different types of customers, such 319 as residential customers, commercial customers and industrial 320 customers, have been provided. The ZIP coefficients in Table I 321 (adopted from [28]) are used in this paper.

D. Centralized Coordination Model

s.t.

(8)

In this section, a centralized optimization model is presented 323 to coordinate the fast-dispatch of PV inverters and the slow- 324 dispatch of conventional voltage regulation devices (OLTC and 325 CBs) to facilitate voltage reduction in unbalanced distribu- 326 tion systems. This model will be decomposed into bus-level 327 sub optimization problems in Section IV to design a dis- 328 tributed ADMM-based solver. The status of CBs and OLTC 329 are scheduled at the beginning of every hour to manage the 330 slow voltage variations, then the on-off status of CBs and 331 tap of OLTCs are fixed for the rest of this hour within the 332 optimization solver. In other words, no intra-hour decision 333 instant is defined for CBs and OLTC. Within each hour, 334 PV inverters are dispatched every 15 minutes to handle the 335 faster voltage deviations. Hence, intra-hour decision instants 336 are defined for PV inverters. 337

$$\min_{V_i, P_i, Q_i} \left(w_1 \sum_{i=1}^N \left(V_{i,\phi}^* \right) + w_2 \sum_{i=1}^N \left(loss_{i,\phi} \right) \right)$$
(10) 338

339

322

$$V_{i,\phi}^* \ge \max_{t \in T} \left(V_{i,t,\phi} \right) \tag{11}$$

$$loss_{i,\phi} = \sum_{t=1}^{T} \left(r_{i,\phi} \frac{\left(P_{i,t,\phi}^{l} \right)^{2} + \left(Q_{i,t,\phi}^{l} \right)^{2}}{V_{s}^{2}} \right)$$
(12) 341

$$P_{i,t,\phi}^{l} = P_{i-1,t,\phi}^{l} - P_{i,t,\phi}^{ZIP} + P_{i,t,\phi}^{pred}$$
(13) 342

$$P_{i,t,\phi}^{I} = P_{i,t,\phi}^{P,rea} - \varepsilon_{i,t,\phi}$$
(14) 343

$$Q_{i,t,\phi}^{l} = Q_{i-1,t,\phi}^{l} - Q_{i,t,\phi}^{ZIP} + Q_{i,t,\phi}^{PV} + Q_{i,t}^{CB}$$
(15) 344

$$q^{*}_{i,t,\phi} = \mathcal{Q}_{i,t,\phi} \leq q_{i,t,\phi}$$
(10) 345
$$q^{*}_{i,t,\phi} = \sqrt{\left(S^{PV}\right)^{2} - \left(P^{pred}\right)^{2}}$$
(17) 345

$$q_{i,t,\phi}^{CB} = \sqrt{\begin{pmatrix} S_{i,t,\phi}^{CB} \end{pmatrix}} - \begin{pmatrix} P_{i,t,\phi} \end{pmatrix}$$

$$(17)_{346}$$

$$Q_{i,t,\phi}^{CB} = I_{i,t,\phi}^{CB}$$

$$(18)_{347}$$

$$P_{i,t,\phi}^{ZIP} = P_{i,t,\phi}^{D} \left(Z_{i}^{p} V_{i,t,\phi}^{2} + I_{i}^{p} V_{i,t,\phi} + P_{i}^{p} \right)$$
(19) 348

$$Q_{i,t,\phi}^{ZIP} = Q_{i,t,\phi}^{D} \left(Z_{i}^{q} V_{i,t,\phi}^{2} + I_{i}^{q} V_{i,t,\phi} + P_{i}^{q} \right)$$
(20) 349

$$V_{i,t,\phi} = V_{i-1,t,\phi} - \frac{r_{i-1,\phi}P_{i-1,t,\phi}^l + x_{i-1,\phi}Q_{i-1,t,\phi}^l}{V_s}$$
(21) 350

$$V_{1,t} = V_s + I_t^{tap} V^{tap} \tag{22} \quad 351$$

$$\sum_{i,t}^{\min} \leq V_{i,t,\phi} \leq V_{i,t}^{\max}$$

$$\sum_{i,t} |I^{CB} - I^{CB}| \leq CB^{\max}$$

$$(23) \quad 352$$

$$\sum_{t \in T} |T_{i,t} - T_{i,t-1}| \le CD$$
(24) 353
$$\sum_{t \in T} |T_{i,t-1}| \le CD$$
(25)

$$\sum_{t \in T} |I_t^{(ap)} - I_{t-1}^{(ap)}| \le TAP^{max}$$
(25) 354

$$I_t^{mp} \in \{-10, -9, \cdots, 0, \cdots, 9, 10\}$$
 356

$$\forall i \in \Omega_N, \forall t \in \Omega_T, \forall \phi \in \Omega_\phi$$
³⁵⁷

In the above formulations, $V_{i,t,\phi}$, $P_{i,t,\phi}^l$, $Q_{i,t,\phi}^l$, as well as ³⁵⁸ other variables and parameters are modeled in three-phase, ³⁵⁹ e.g., $V_{i,t,\phi} = [V_{i_a,t}, V_{i_b,t}, V_{i_c,t}]^T$. The same applies to network ³⁶⁰ parameters, e.g., $r_{i,\phi}$, $x_{i,\phi} \in \Omega^{3\times3}$. ³⁶¹

In order to investigate the trade-off between the voltage (or load) reduction and real power loss reduction, we have included two components in the objective function (10): one component is aimed at minimization of the largest bus voltage and the other is defined to minimize the active line losses during the dispatch period. It is assumed that the two components are weighted by factors w_1 and w_2 ($0 \le w_1, w_2 \le 1$, $w_1 + w_2 = 1$), respectively. The distribution system operators can adjust the weighting factors w_1 and w_2 according to w_1 specific operational requirements.

Constraint (11) aims to find the largest voltage magnitude 372 $_{373}$ at bus *i* at time *t*. Equation (12) determines the overall active ³⁷⁴ power losses on the line connecting bus *i* and bus i - 1 at *t*. 375 Equation (13) is the nodal active power balance formulation, which includes the active power in-flow and out-flow at bus *i*, 376 377 active power output of PV inverter, as well as the ZIP active 378 load of bus *i*. Here, the reactive power outputs of PV invert- $_{379}$ ers $(Q_{i,t,\phi}^{PV})$ will be dispatched considering the predicted active solar PV generation $(P_{i,t,\phi}^{pred})$. The uncertainty of PV power 381 is represented by Gaussian random variables for PV power ³⁸² prediction error. Accordingly, each agent predicts the available 383 nodal PV power over the decision window. Due to the uncer-384 tainty of PV power in real-time, the predicted value is different 385 from the actual PV power. The difference is modeled using a ³⁸⁶ Gaussian error variable as shown in equation (14), where $P_{i,t,\phi}^{pred}$ _{1,i, ψ} and $P_{i,t,\phi}^{PV}$ denote the predicted and actual active power output 388 of PV, $\varepsilon_{i,t,\phi} \sim N(0,\sigma)$ denotes the Gaussian prediction error. ³⁸⁹ The standard deviation of the error variable, ε , is chosen based ³⁹⁰ on [30]. Note that the optimization problem is solved using the ³⁹¹ predicted PV power. Hence, the prediction error, which reflects ³⁹² the impact of PV power uncertainty, leads to slight deviation ³⁹³ (less than 1%) from the true optimal solution. This deviation ³⁹⁴ depends mainly on the quality of the prediction captured by 395 the prediction error standard deviation. Equation (15) is the 396 nodal reactive power balance formulation, which determines ³⁹⁷ the reactive power output of PV inverter at bus i and reactive ³⁹⁸ power output of CB at bus *i*. Constraint (16) and equation (17) ³⁹⁹ limit the reactive power capacity of PV inverters based on PV 400 generation capacity and the active power output. Combining 401 constraints (15), (16) and (17), we can obtain (26) and (27). ⁴⁰² Now we can obtain $Q_{i,t,\phi}^{PV}$ by using the optimal results and the ⁴⁰³ nodal reactive power balance equations.

404
$$Q_{i,t,\phi}^l - Q_{i-1,t,\phi}^l + Q_{i,t,\phi}^{ZIP} - Q_{i,t}^{CB} - q_{i,t}^* \le 0$$

$$-Q_{i,t,\phi}^{l} + Q_{i-1,t,\phi}^{l} - Q_{i,t,\phi}^{ZIP} + Q_{i,t}^{CB} - q_{i,t}^{*} \le 0$$
(27)

Equation (18) obtains the CB reactive power injection at 407 bus *i*. $I_{i,t}^{CB}$ represents the on/off status of the CB at bus *i* during 408 the dispatch period *T*. For buses without CB, q_i^{CB} is set to zero. 409 Equations (19) and (20) represent the ZIP active and reactive 410 load by second-order polynomial formulations. Summation of 411 ZIP coefficients for both active and reactive are set to 1. $P_{i,t,\phi}^D$ 412 and $Q_{i,t,\phi}^D$ are active and reactive power demand factors during 413 the dispatch period, respectively. Equation (21) determines the 414 bus voltage using DistFlow equations.

Equation (22) determines the substation transformer sec-416 ondary voltage according to primary voltage V_s and OLTC tap 417 position I_t^{tap} . Constraint (23) guarantees that the bus voltage is maintained within the allowable range, and the voltage limits $_{418}$ are set to be [0.95, 1.05]. Constraints (24) and (25) denote $_{419}$ the maximum allowable switching actions of CBs and OLTC $_{420}$ during the dispatch period. For example, in the following case $_{421}$ studies, the *CB^{max}* is set to be 3 and *TAP^{max}* is set to be 5. $_{422}$ In order to reduce the non-linearity of the absolute values, $_{423}$ constraints (24)-(25) are transformed into linear forms. $_{424}$

III. DISTRIBUTED OPTIMIZATION METHOD

In this section, the centralized coordination model of 426 PVs with OLTC and CBs is decomposed into bus-level 427 sub-problems. A modified ADMM is introduced to handle the 428 non-convex problem with discrete variables of CBs and OLTC. 429

A. Modified ADMM

Discrete variables $I_{i,t}^{CB}$ and I_t^{tap} are used in the centralized VVO formulations (10)-(25). However, the conventional ADMM is originally developed to solve convex problems. A simple solution to address this problem is to relax the discrete variables to continuous ones. However, this approach cannot ensure a high-quality solution in general. Instead, in [24] 436 a modified ADMM has been proposed, which includes the auxiliary equality constraints with discrete variables as of the optimization objective function, and finds the best match for discrete variables in the ADMM iterative update process. 440 Numerical results have shown that this modified ADMM has 441 better performance in handling discrete variables compared to simple relax-and-round methods [24].

Considering the optimization problem (28)-(30), first, discrete variable I is replaced with an auxiliary continuous 445 variable y in constraint (29); then, an additional auxiliary 446 equality is introduced as constraint (30). 447

$$\min_{x,I} f(x,I)$$
(28) 448

s.t.

(26)

$$I = v$$
 (29) as

$$7 = g(x, y)$$
 (30) 450

$$I \in \mathbb{Z}, x, y \in \mathbb{R}$$

$$452$$

After decomposition, the augmented Lagrangian for this $_{453}$ problem is shown in (31), where $\rho>0$ is the penalty $_{454}$ coefficient.

$$\mathcal{L}_{\rho} = f(x_i, y_i) + \lambda_i^z (z_i - g(x_i, I_i)) + \frac{\rho}{2} \|z_i - g(x_i, I_i)\|_2^2 \quad (31) \quad {}_{456}$$

Therefore, the modified ADMM iterative update 457 rules (32)-(34) for optimization problem (28)-(30) can 458 be presented as follows (with the iteration number denoted 459 by *k*):

$$(x_i(k+1), y_i(k+1)) = \underset{x, y}{\operatorname{argmin}} \mathcal{L}_{\rho}(x_i, y_i, \lambda_i^z(k))$$
(32) 461

$$I_i(k+1) = \underset{I}{\operatorname{argmin}} \|z_i(k+1) - g(x_i(k+1), I_i)\|_2^2$$
(33) 462

$$\lambda_i^z(k+1) = \lambda_i^z(k) + \rho(z_i(k+1) - g(x_i(k+1), I_i(k+1))).$$
(34)
(34)

430

449

425

465 B. Distributed Solution Algorithm

The centralized optimization problem (10)-(25) can be 466 467 decomposed to a set of bus-level small-size optimization problems. Bus-level control agents are in charge of manag-468 ⁴⁶⁹ ing the local controllable resources and local voltage at each 470 bus. This takes place through sharing estimated local solutions with neighboring agents using the proposed modified ADMM 471 472 solution strategy. Each bus agent solves a local optimization ⁴⁷³ problem, which has its own *local variables* $P_{i,t,\phi}^l$, $Q_{i,t,\phi}^l$, $V_{i,t,\phi}$, as well as the *copy variables* $P_{j,t,\phi}^l$, $Q_{j,t,\phi}^l$, $V_{j,t,\phi}^{l}$ exchanged between neighboring buses *j* to bus *i*. The buses installed with 474 475 CBs or OLTC have discrete variables $I_{i,t}^{CB}$ and I_t^{tap} . 476

Therefore, with auxiliary variables and equality constraints, the original optimization problem can be decomposed into buslevel optimization problems. The constraints (11)-(25) can be reformulated as (11)*-(25)* by replacing the variables by their corresponding auxiliary variables.

$$\min_{U_i \mid P_i \mid O_i} f(X_i, I_i) \tag{35}$$

483 S.t.

482

$$P_{i,t,\phi}^{l} = P_{i,t,\phi}^{+}, P_{j,t,\phi}^{l} = P_{i,t,\phi}^{-}$$
(36)

485
$$Q_{i,t,\phi}^{l} = Q_{i,t,\phi}^{+}, Q_{j,t,\phi}^{l} = Q_{i,t,\phi}^{-}$$
 (37)

486
$$V_{i,t,\phi}^2 = U_{i,t,\phi} = U_{i,t,\phi}^+, V_{j,t,\phi}^2 = U_{j,t,\phi} = U_{i,t,\phi}^-$$
 (38)

$$\begin{array}{ll}
{487} & I{i,t}^{CB} = y_{i,t}^{CB}, I_t^{-1} = y_t^{-1} \\
{488} & z{1,i} = g_1 \left(X_i, y_{i,t}^{CB} \right) \\
\end{array} \tag{39}$$

$$z_{1,i} = g_1(x_i, y_{i,t})$$

$$z_{2,i} = g_2(X_i, y_t^{tap})$$
(41)

491
$$\forall i \in \Omega_N, \forall j \in \Omega_i, \forall t \in \Omega_T, \forall \phi \in \Omega_{\phi}$$

 $(11)^* - (25)^*$

For convenience, four variable sets are defined at 493 each bus to exchange information with agents at 494 neighboring buses. Let the variable set X_i include 495 $P_{i,t,\phi}^+, P_{i,t,\phi}^-, Q_{i,t,\phi}^+, Q_{i,t,\phi}^-, U_{i,t,\phi}^+, U_{i,t,\phi}^-$, the variable set I_i 496 include $I_{i,t}^{CB}, I_i^{tap}$, the variable set Y_i include $y_{i,t}^{CB}, y_t^{tap}$ and 497 the variable set λ_i include $\lambda_{i,t,\phi}^{P^+}, \lambda_{i,t,\phi}^{Q^+}, \lambda_{i,t,\phi}^{Q^+}, \lambda_{i,t,\phi}^{Q^-}, \lambda_{i,t,\phi}^{U^+}, \lambda_{i,t,\phi}^{Q^-}, \lambda_{i,t,\phi}$

To apply the modified ADMM to the proposed central-⁵⁰⁰ ized coordination model (35)-(41) and $(11)^* - (25)^*$, the ⁵⁰¹ distributed iterative process has been presented as (42)-(57) ⁵⁰² in four steps. Fig. 3 shows the process of local optimization ⁵⁰³ solution exchanges between neighboring buse agents in the ⁵⁰⁴ distributed algorithm. The convergence criteria is set by a ⁵⁰⁵ maximum iteration limit.

Step 1: For each bus agent *i* at iteration *k*, local optimization problems, shown in (42), are solved independently and in parallel. Solutions to bus local variables X_i and Y_i are obtained.

⁵⁰⁹
$$(X_i(k+1), Y_i(k+1)) = \underset{X,Y}{\operatorname{argmin}} \mathcal{L}_{\rho}(X_i, Y_i, \lambda_i(k)).$$
 (42)

Step 2: For each bus agent *i* at iteration *k*, local optimization
 solution exchanges take place between neighboring agents to
 update variables based on respective bus local variables and
 variables at buses connected to bus *i*, which are obtained from
 step 1.

Fig. 3. Local optimization solution exchange between control agents at different buses.

Hence, variable set X_i is updated by averaging the respective 515 local bus variables and using (43)-(45), where n_i denotes the 516 number of buses connected to bus *i* plus 1: 517

$$P_{i,t,\phi}^{l}(k+1) = \frac{1}{2} \left(P_{i,t,\phi}^{+}(k+1) + P_{i,t,\phi}^{-}(k+1) \right)$$
(43) 510

$$Q_{i,t,\phi}^{l}(k+1) = \frac{1}{2} \Big(Q_{i,t,\phi}^{+}(k+1) + Q_{i,t,\phi}^{-}(k+1) \Big)$$
(44) 519

$$U_{i,t,\phi}(k+1) = \frac{1}{n_i} \left(U_{i,t,\phi}^+(k+1) + \dots + U_{i,t,\phi}^-(k+1) \right)$$
(45) 520

Variables $I_{i,t}^{CB}$ and I_t^{Iap} are updated by solving local bus 521 optimization problems using $X_i(k+1)$ and $Y_i(k+1)$ as shown 522 in (46) and (47): 523

$$I_{i,t}^{CB}(k+1) = \underset{I_{i,t}}{\operatorname{argmin}} \left\| z_{1,i}(k+1) - g_1 \left(X_i(k+1), I_{i,t}^{CB} \right) \right\|_2^2$$
 524

$$I_t^{tap}(k+1) = \underset{I_t}{\operatorname{argmin}} \left\| z_{1,i}(k+1) - g_2 \left(X_i(k+1), I_t^{tap} \right) \right\|_2^2.$$
 526

Step 3: For each bus *i* at iteration *k*, the Lagrange multipliers ⁵²⁸ are updated based on the ADMM iterative rules and the ⁵²⁹ variables obtained in previous steps. Hence, the Lagrange ⁵³⁰ multipliers for variable set X_i are updated using (48)-(53): ⁵³¹

$$\lambda_{i,t,\phi}^{P^+}(k+1) = \lambda_{i,t,\phi}^{P^+}(k) + \rho \left(P_{i,t,\phi}^+(k+1) - P_{i,t,\phi}^l(k+1) \right)$$
(48) 532

$$\lambda_{i,t,\phi}^{P^-}(k+1) = \lambda_{i,t,\phi}^{P^-}(k) + \rho \left(P_{i,t,\phi}^-(k+1) - P_{j,t,\phi}^l(k+1) \right) \tag{49}$$

$$\lambda_{i,t,\phi}^{Q^+}(k+1) = \lambda_{i,t,\phi}^{Q^+}(k) + \rho \left(Q_{i,t,\phi}^+(k+1) - Q_{i,t,\phi}^l(k+1) \right)$$
(50) 537

$$\lambda_{i,t,\phi}^{Q^-}(k+1) = \lambda_{i,t,\phi}^{Q^-}(k) + \rho \Big(Q_{i,t,\phi}^-(k+1) - Q_{j,t,\phi}^l(k+1) \Big)$$
(51) 538

$$\lambda_{i,t,\phi}^{U^{+}}(k+1) = \lambda_{i,t,\phi}^{U^{+}}(k) + \rho \left(U_{i,t,\phi}^{+}(k+1) - U_{i,t,\phi}(k+1) \right)$$

$$\lambda_{i,t,\phi}^{U^{-}}(k+1) = \lambda_{i,t,\phi}^{U^{-}}(k) + \rho \left(U_{i,t,\phi}^{-}(k+1) - U_{j,t,\phi}(k+1) \right)$$

$$\lambda_{i,t,\phi}^{U^{-}}(k+1) = \lambda_{i,t,\phi}^{U^{-}}(k) + \rho \left(U_{i,t,\phi}^{-}(k+1) - U_{j,t,\phi}(k+1) \right)$$

$$\lambda_{i,t,\phi}^{U^{-}}(k+1) = \lambda_{i,t,\phi}^{U^{-}}(k) + \rho \left(U_{i,t,\phi}^{-}(k+1) - U_{j,t,\phi}(k+1) \right)$$

$$\lambda_{i,t,\phi}^{U^{-}}(k+1) = \lambda_{i,t,\phi}^{U^{-}}(k) + \rho \left(U_{i,t,\phi}^{-}(k+1) - U_{j,t,\phi}(k+1) \right)$$

$$\lambda_{i,t,\phi}^{U^{-}}(k+1) = \lambda_{i,t,\phi}^{U^{-}}(k) + \rho \left(U_{i,t,\phi}^{-}(k+1) - U_{j,t,\phi}(k+1) \right)$$

$$\lambda_{i,t,\phi}^{U^{-}}(k+1) = \lambda_{i,t,\phi}^{U^{-}}(k) + \rho \left(U_{i,t,\phi}^{-}(k+1) - U_{j,t,\phi}(k+1) \right)$$

$$\lambda_{i,t,\phi}^{U^{-}}(k) = \lambda_{i,t,\phi}^{U^{-}}(k) + \rho \left(U_{i,t,\phi}^{-}(k+1) - U_{j,t,\phi}(k+1) \right)$$

$$\lambda_{i,t,\phi}^{U^{-}}(k) = \lambda_{i,t,\phi}^{U^{-}}(k) + \rho \left(U_{i,t,\phi}^{-}(k+1) - U_{j,t,\phi}(k+1) \right)$$

$$\lambda_{i,t,\phi}^{U^{-}}(k) = \lambda_{i,t,\phi}^{U^{-}}(k) + \rho \left(U_{i,t,\phi}^{-}(k+1) - U_{j,t,\phi}(k+1) \right)$$

Lagrange multipliers for auxiliary equality constraints cor-545 responding to Y_i and I_i are updated using (54) and (55):

546
$$\lambda_{i,t}^{y^{CB}}(k+1) = \lambda_{i,t}^{y^{CB}}(k) + \rho\left(y_{i,t}^{CB}(k+1) - I_{i,t}^{CB}(k+1)\right)$$
 (54)

547
$$\lambda_t^{y^{tap}}(k+1) = \lambda_t^{y^{tap}}(k) + \rho\left(y_t^{tap}(k+1) - I_t^{tap}(k+1)\right)$$
 (55)

Lagrange multipliers for auxiliary equality constraints $g_1(.)$ 549 and $g_2(.)$ are updated using (56) and (57):

$$\sum_{i=1}^{550} \lambda_i^{z1}(k+1) = \lambda_i^{z1}(k) + \rho \left(z_{1,i}(k+1) - g_1 \left(X_i(k+1), I_{i,t}^{CB}(k+1) \right) \right)$$

$$(56)$$

$$\sum_{i=1}^{552} \lambda_i^{z^2}(k+1) = \lambda_i^{z^2}(k) + \rho\Big(z_{2,i}(k+1) - g_2\Big(X_i(k+1), I_t^{tap}(k+1)\Big)\Big).$$

$$(57)$$

Step 4: Increase *k* by 1 till it reaches the maximum iteration number.

IV. CASE STUDY

556

In this section, the convergence analysis and simulation 557 558 results of our proposed method are presented. First, we present the convergence analysis to show the impact of dif-559 ⁵⁶⁰ ferent penalty parameter ρ on convergence speed. We then ⁵⁶¹ demonstrate the effectiveness of our proposed method through 562 numerical evaluations on three IEEE standard benchmarks study load/loss reduction through CVR implementation. 563 to Comparison between centralized optimization and proposed 564 565 distributed optimization is also provided. All the case studies are simulated using a PC with Intel Core i7-4790 3.6 GHz 566 567 CPU and 16 GB RAM hardware. The simulations are performed in MATLAB and GAMS to solve and update local variables in the iterative distributed optimization process. The 569 main benefit of CVR for utilities is peak loading relief of 570 distribution networks [31]-[33]. In this paper, the CVR is 571 used for peak load reduction by modifying the voltages of 572 573 the system buses through finding optimal switching and con-574 trol actions for CBs and OLTCs, as well as reactive power 575 injection/absorption set points for PV inverters. Given the voltage-sensitivity of active power (see the ZIP coefficients) 576 577 these control actions, if chosen correctly, lead to a drop in 578 consumption at critical times, such as the peak interval. In all 579 the simulations, the CVR functionality was tested over 3 hours 580 of peak load period with 15-minute time steps.

581 A. Case I: Convergence Analysis (IEEE 13-Bus System)

In order to perform convergence studies, the proposed method is implemented on IEEE 13-bus system and the results results for different values of ρ . Within certain range of ρ , the proposed algorithm can converge faster with larger ρ values. However, increasing ρ to a too large value will cause numerical instability and divergence.

Fig. 4. Convergence of the distributed optimization: Impact of different penalty parameter ρ values.

Fig. 5. Convergence of the distributed optimization: Iterative updates of bus voltage magnitudes ρ =5.

Fig. 6. Convergence of the distributed optimization: Iterative updates of PV inverter reactive power outputs ρ =5.

The iterative updates of bus voltages with $\rho = 5$ are shown 5699 in Fig. 5. All the optimal voltage magnitudes have converged 590 to values within [0.95 p.u., 1.05 p.u.] interval, which satisfies 591 the bus voltage limit constraints. Fig. 6 presents the iterative 592 updates of three-phase reactive power outputs of PV inverters 593 with $\rho = 5$. It can be seen that most of variables converge 594 after 3000 iterations, while only a few take more than 4000 595 iterations to converge. 596

B. Case II: IEEE 34-Bus Distribution System

The results of simulation studies on modified IEEE 34-bus 598 distribution system (Fig. 7) are presented in this section. 599 Details about this test network can be found in [34]. It is 600 assumed that the substation OLTC is within $\pm 10\%$ tap range. 601

597

Fig. 7. Case II: Modified IEEE 34-bus test distribution system.

TABLE II					
CASE	II:	BUS	TYPE		

Fig. 8. Case II: Optimal results with full implementation of CVR (a)-(c) PV inverter three-phase reactive power outputs.

⁶⁰² Two three-phase CBs are installed at buses 27 and 29, and ⁶⁰³ the CB capacities are the same as the original system. The ⁶⁰⁴ PV generations are aggregated at buses 24, 30 and 32. It is ⁶⁰⁵ assumed that the PV at each bus can provide 60% of load at ⁶⁰⁶ the bus to ensure that the PV capacities and outputs are dif-⁶⁰⁷ ferent from each other. For comparison, a base case without ⁶⁰⁸ any VVO is defined, where unity-power factor control mode ⁶⁰⁹ is used for PVs, the tap position of OLTC is fixed, and CB ⁶¹⁰ status is on.

The bus types are listed in Table II and the corresponding ZIP load coefficients for different load types are presented in Table I [28]. The proposed modified ADMM method is applied to the test system with full implementation of CVR, which implies the weight factors $w_1 = 1, w_2 = 0$. Fig. 8

TABLE III Case II: Optimal Results of CB Switching States and OLTC Tap Positions

CB position	Hour 1	Hour 2	Hour 3
Bus 27	0	1	0
Bus 29	1	1	1
Substation OLTC	-4	-4	-3

TABLE IV Case II: Comparison Results Between Centralized Opt. and Modified ADMM

	Centralized Opt.	Modified ADMM
Load reduction	3.79%	3.84%
CPU time	623.0s	235.3s

shows the results of three phase PV inverter reactive power $_{616}$ outputs, which change each 15 minutes based on the latest $_{617}$ system information. Table III demonstrates that in order to $_{618}$ overcome the voltage drop problems caused by CVR effects, $_{619}$ the CB on bus 27 is only needed on the second hour of peak $_{620}$ load interval, the CB on bus 29 is always on, and the substation $_{621}$ OLTC tap position varies between tap -3 and -4. Note the $_{622}$ difference between the decision timescales of PV inverters on $_{623}$ the one hand, and CBs/OLTC on the other hand. $_{624}$

A numerical comparison is presented in Table IV between 625 a centralized solver versus the proposed modified distributed 626 ADMM for optimization (10)-(25) tested on the modified 627 34-bus test system. It can be seen that the percentage of load 628 reduction from the centralized optimization and the proposed 629 modified ADMM are very similar to each other, with ADMM 630 yielding slightly better results. More importantly, the aver- 631 age computational time per agent per iteration of our method 632 is 0.235 seconds and the average convergence iteration is 633 around 1000. Therefore, in terms of computational efficiency, 634 the distributed ADMM takes approximately one third of the 635 computational time of centralized solver to reach comparable 636 and slightly better results. This demonstrates the advantage 637 of the proposed distributed optimization technique for real- 638 time applications. Other computational benefits of ADMM are 639 discussed in detail in [35] and [36]. 640

In the next step, the proposed solution method is applied ⁶⁴¹ to the test system model with varying weight factors for the ⁶⁴² components of the objective function (load reduction versus ⁶⁴³ loss reduction). As discussed before, CVR implementation ⁶⁴⁴ defines a trade-off between voltage reduction and real power ⁶⁴⁵ loss reduction, which needs to be numerically quantified. Five ⁶⁴⁶ different cases, named as *Opt. 1* to *Opt. 5*, are defined with different weight values (w_1 , w_2), varying from (1,0), (0.75,0.25), ⁶⁴⁸ (0.5,0.5), (0.25,075) to (0,1). The cases *Opt. 1* to *Opt. 5* ⁶⁴⁹ represent the variation of objective function from full implementation of bus voltage minimization to full implementation ⁶⁵¹ of power loss minimization.

The total energy reduction is calculated as the summation 653 of load power reduction and power loss reduction. The total 654 energy reduction for *Opt. 1* to *Opt. 5* varies from 2.77% 655 to 0.91%. Fig. 9 shows voltage profiles of ϕ_a for all cases, 656 including the base case, in one snapshot. The optimal voltage 657

Fig. 9. Case II: Voltage profiles at t=1 and for ϕ_A of base case and cases *Opt. 1* to *Opt. 5*.

Fig. 10. Case II: Load power consumption for the base case and cases *Opt. 1* to *Opt. 5*.

⁶⁵⁸ magnitudes of *Opt. 1* to *Opt. 5* are generally lower than the ⁶⁵⁹ base case (black solid line), which shows the voltage reduc-⁶⁶⁰ tion effects of VVO. Due to the optimization constraints and ⁶⁶¹ the impacts of reactive power injection from PV inverters and ⁶⁶² CBs, the optimal voltage magnitude on a number of buses are ⁶⁶³ slightly higher than the base case voltages at some non-critical ⁶⁶⁴ time points. Comparing the optimal bus voltage magnitudes in ⁶⁶⁵ the defined cases, *Opt. 1* shows the lowest bus voltage, which ⁶⁶⁶ demonstrates the CVR impact on voltage reduction, as a higher ⁶⁶⁷ weight is assigned to voltage minimization component.

Fig. 10 and Fig. 11 present the load power consumption and 668 669 power losses of the base case and CVR cases Opt. 1-Opt. 5, 670 respectively. As can be observed for the case of Opt. 1, the highest load reduction at peak time is achieved since a higher 671 672 eight is assigned to the load reduction objective in equa-673 tion (10). Among the cases Opt. 1-Opt. 5 and the base case, Opt. 1 has the largest load reduction and Opt. 5 has the largest 674 675 loss reduction, which shows the effect of various w_1 and w_2 , 676 respectively. Hence, it is corroborated that by changing the weight factors in the optimization model the trade-off between 677 678 CVR and loss minimization in the final decision solution can 679 be controlled effectively.

In order to further investigate the impact of CVR on power losses, three cases with different ZIP coefficients have been introduced. *ZIP1* represents the general active and reactive ZIP loads with coefficients [0.4, 0.3, 0.3]. Two extreme cases *ZIP2* and *ZIP3* represent pure constant impedance active/reactive loads with coefficients [1, 0, 0], and pure constant power active/reactive loads with coefficients [0, 0, 1], respectively. In Table V, loss reduction levels, load reduction levels and

Fig. 11. Case II: Power losses for the base case and cases Opt. 1 to Opt. 5.

TABLE V Case II: Summary of System Loss, Load and Total Energy Reduction With Different ZIP Coefficients and Weight Factors

	Casas		Loss	Load	Total
	Cases		reduction	reduction	reduction
	7101	Opt.1	2.62%	4.07%	3.93%
		Opt.2	4.52%	3.82%	3.89%
	ZIPI	Opt.3	10.21%	3.17%	3.87%
	(0.4,0.5,0.5)	Opt.4	14.04%	2.62%	3.75%
		Opt.5	18.53%	1.01%	2.74%
		Opt.1	1.82%	5.53%	5.11%
	7100	Opt.2	4.47%	5.07%	4.95%
	ZIP2	Opt.3	6.47%	4.66%	4.78%
	(1,0,0)	Opt.4	7.84%	4.12%	4.43%
		Opt.5	9.90%	3.44%	4.01%
		Opt.1	-3.28%	0.00%	-0.36%
	7102	Opt.2	-1.87%	0.00%	-0.20%
	ZIP3	Opt.3	-1.48%	0.00%	-0.16%
	(0,0,1)	Opt.4	-0.50%	0.00%	-0.05%
		Opt.5	3.98%	0.00%	0.43%

total energy reduction have been shown for Case II and under 688 different ZIP models, *ZIP1*, *ZIP2*, *ZIP3*, and with different 689 optimization weight assignment scenarios, *Opt. 1-Opt. 5*. 690

Based on the results from Table V and Fig. 12, it can be 691 observed that for *ZIP1* and *ZIP2*, loss reduction levels are 692 increasing from *Opt. 5* to *Opt. 1*, however, the load reduction 693 and total energy reduction decrease at the same time. Since 694 *ZIP3* represents pure constant power loads, consumption levels 695 are always the same as the base case regardless of bus voltage levels, and the loss reduction and total energy reduction 697 increase for *Opt. 1* to *Opt. 5*. Therefore, for voltage-dependent 698 loads, *ZIP1* and *ZIP2*, load reduction (due to voltage reduction) accounts for the majority of the change in total energy 700 savings. On the other hand, since CVR has no impact on the 701 constant power loads, *ZIP3*, for that case load reduction is 702 zero and the loss optimization is the only effective method to 703 reduce the peak demand. 704

C. Case III: IEEE 123-Bus Distribution System

To test our proposed distributed algorithm on a larger 706 system, simulation results for modified IEEE 123-bus distri- 707 bution system (Fig. 13) with a higher number of PV inverters, 708 CBs and OLTCs are shown in this section. Details about this 709 test network can be found in [34]. The locations of OLTCs 710

 TABLE VI

 Case III: Locations and Capacities of Devices

Туре	Locations	Capacities
PV	5, 9, 14, 15, 18, 29, 31, 39, 41, 46, 51, 57, 62, 69, 82, 86, 95, 103, 106, 112	20 kVAr per ϕ_a, ϕ_b, ϕ_c
СВ	83, 88, 90, 92	{200, 200, 200}, {50, 0, 0}, {50, 0, 0}, {50, 0, 0} kVAr
OLTC	9, 25, 120, 150	Tap $\in \{-10, -9 \cdots 0 \cdots 9, 10\}$

711 are set to be the same as [18]. The locations and capacities 712 of CB are selected based on the original settings in [34]. The 713 locations of PV are adopted from [37]. Table VI summarizes 714 the types, locations and capacities of the devices integrated in 715 the system.

The proposed method is applied to the modified 123-bus test r17 system with ZIP coefficients [0.4, 0.3, 0.3] for both active and r18 reactive loads, and full implementation of CVR ($w_1 = 1$). r19 In order to show the convergence process, Fig. 14 shows r20 the average iteration-wise updates in voltage magnitude, i.e., r21 $V_{i,t,\phi}^*(k) = V_{i,t,\phi}(k+1) - V_{i,t,\phi}(k)$ with *k* being the iteration r22 index. It can be seen that voltage residues V^* converge to r23 zero as the iteration number, *k*, increases. Hence, the algorithm

		Opt.5	2.70%	0.00%	0.51%

converges to optimal solution within an acceptable number of 724 iterations in a reasonable time.Based on our numerical exper-725 iments, the average computational time per agent per iteration 726 for the IEEE 123-bus system is 0.245 seconds. Hence, the 727 overall algorithm takes around 6 minutes to converge (ignor-728 ing communication delays) for this test system. On the other 729 hand, the selected time step for the simulation is t = 15 min-730 utes, which is well above the required algorithm convergence 731 time. Hence, the distributed algorithm is well capable of reach-732 reason that a time step of 15 minutes was selected is that this 734 time step is consistent with the frequency measurement of 735 current smart meters used in the industry. 736

In Table VII, the total network loss reduction, load reduction 737 and total energy for different categories of load, *ZIP1*, *ZIP2*, 738 and *ZIP3*, have been shown as a function of different weight 739 values assigned to optimization objective components. As can 740 be seen in this table, similar trends are observed as those of 741 the smaller case study (Case II) shown in Table V: for voltagedependent loads *ZIP1* and *ZIP2*, loss reduction levels increase 743 from *Opt. 1* through *Opt. 5*, and the load reduction and total 744 energy reduction decrease in *Opt. 1* through *Opt. 5*; for constant power load *ZIP3*, load consumption levels are always 746 ⁷⁴⁷ the same as the base case, and the loss reduction and total ⁷⁴⁸ energy reduction increase in *Opt. 1* through *Opt. 5*. In addi-⁷⁴⁹ tion, more load reduction is achieved for this case. Therefore, ⁷⁵⁰ the conclusions drawn in Section IV-B regarding the trade-⁷⁵¹ off between voltage magnitude optimization and network loss ⁷⁵² reduction under different ZIP characteristics are again verified ⁷⁵³ for the larger IEEE 123-bus test system.

V. CONCLUSION

A distributed method is developed to optimally coordinate 755 756 the fast-dispatch of PV inverters with the slow-dispatch of 757 OLTC and CBs for CVR in three-phase unbalanced distribu-758 tion systems. The trade-off between voltage reduction (load 759 reduction) and real power loss minimization is analyzed by the developed multi-objective VVO formulation. The proposed 760 VO-based CVR is solved by distributed optimization algo-V 761 762 rithm ADMM, which can maintain customer data privacy and alleviate computational burden in large-scale distribution 763 764 networks. In order to better handle the non-convexity of the 765 decision problem caused by discrete variables, the distributed 766 algorithm ADMM is modified in a way that the discrete vari-767 ables are not only relaxed into continuous variables, but also 768 implemented as a generalized part of the objective function 769 in the iterations to avoid sub-optimality. According to case 770 studies, our proposed method can converge within an accept-771 able number of iterations for large unbalanced distribution 772 systems. It is also observed that different load types affect the 773 CVR performance differently. Among different load types, the 774 highest levels of the CVR-based consumption reduction are 775 achieved for voltage-sensitive loads. Also it is demonstrated 776 that as the penetration of voltage-sensitive customers increases, CVR could be a better option for energy saving at substation 777 778 level during peak load interval, compared to mere network loss 779 minimization.

Qianzhi Zhang (S'17) received the B.S. degree in electrical and computer engineering from the Shandong University of Technology in 2012 and the M.S. degree in electrical and computer engineering from Arizona State University in 2015. He is currently pursuing the Ph.D. degree with the Department of Electrical and Computer Engineering, Iowa State University, Ames, IA, USA. From 2015 to 2016, he was a Research Engineer with Huadian Electric Power Research Institute, Hangzhou, China. His research interests include power distribution 910 systems, microgrids, applications of distributed optimization, and machine

911 learning in power systems.

Kaveh Dehghanpour (S'14-M'17) received the 912 B.Sc. and M.S. degrees in electrical and computer 913 engineering from the University of Tehran in 2011 914 and 2013, respectively, and the Ph.D. degree in elec- 915 trical engineering from Montana State University 916 in 2017. He is currently a Post-Doctoral Research 917 Associate with Iowa State University. His research 918 interests include application of machine learning and 919 data-driven techniques in power system monitoring 920 and control. 921

power distribution systems, microgrids, renewable integration, power system 933 resilience, and power system modeling. He is the Principal Investigator for a 934 multitude of projects focused on these topics and funded by the National 935 Science Foundation, the Department of Energy, National Laboratories, 936 PSERC, and Iowa Energy Center. He was a recipient of the IEEE Power 937 and Energy Society (PES) General Meeting Best Paper Award in 2017 and 938 the IEEE Industrial Application Society Prize Paper Award in 2016. He is the 939 Secretary of IEEE PES Award Subcommittee. He is an Editor of the IEEE 940 TRANSACTIONS ON SMART GRID and IEEE PES LETTERS. 941
